Abstract: An updated and reviewed checklist of coastal fishes of the Rio Grande do Norte state, northeastern coast of Brazil, is presented. Between 2003 and 2013 the occurrence of fish species were recorded through collection of specimens, landing records of the artisanal fleet, literature reviews and from specimens deposited in ichthyological collections. A total of 459 species from 2 classes, 26 orders, 102 families and 264 genera is listed, with 83 species (18% of the total number) recorded for the first time in the study area. Additionally, *Halichoeres radiatus*, *Lachnolaimus maximus* and *Canthigaster james-tyleri* are reported for the first time in the Brazilian coast and nine other species have their geographic distribution extended.

Key words: ichthyofauna, marine biodiversity, Pisces, Brazilian coast

INTRODUCTION

The Rio Grande do Norte state (RN), extreme northeastern Brazil, is located in an important transition area of north-south oriented coastline that abruptly changes its direction to the east-west. In addition to this abrupt change, marked differences can also be seen along the RN shore. On the northern coast, the climate is semi-arid with annual rainfall less than 750 mm and predominance of northeastern winds (Nimer 1989). There are some sparse areas of beachrocks well apart from each other and three large estuarine complexes with numerous channels. The reefs are parallel to the coast and few in number, but with large areas (e.g., 20 km²). Some reefs are poorly known and even not mapped on the Brazilian Navy nautical charts. On the eastern coast, the climate is warm-humid with annual rainfall reaching 1,250 mm and with southeastern winds prevailing (Nimer 1989). The beachrocks are larger and

more continuous than northern coast, the three major estuaries are small and without many ramifications, and the reefs are more numerous but smaller and relatively closer to each other than northern coast. The first and only checklist of fish species that occur along the coast of RN was produced in 1988 and comprised 190 species (Soares 1988). This situation improved after 2000 with fish surveys in specific sites of the coast (e.g., Feitoza 2001; Feitosa et al. 2002; Moura 2003; Feitoza et al. 2005; Yokota 2005; Dias 2006; Garcia Jr et al. 2010). Although such investigations have contributed to enhance the information about the local ichthyofauna, it is clear that there is a need to include all records in a single and complete list. Here, we provide an updated checklist of the fishes that occur along the coast of RN based on 10 years of collecting specimens, landing records of artisanal fisheries, examinations of fish collections, and reviewing previous studies of the area.

MATERIALS AND METHODS

Study area

Rio Grande do Norte state has about 400 km of coastline divided into a northern coast from Tibau, at the border with Ceará state, to Cabo Calcanhar, and an eastern coast from Cabo Calcanhar to Baía Formosa, at the border with Paraíba state (Figure 1a). The RN coast is under the influence of the surface circulation of the south Atlantic subtropical gyre, where the southern branch of the South Equatorial Current (SEC) flows westward to the Brazilian coast. The SEC bifurcates between 12° and 14° S, forming the North Brazil Current (NBC) to the north and the Brazil Current to the south (Figure 1b). The NBC, although weak, is constant along the Brazilian coast, where at approximately 04° S, 036° W it joins the central branch of the SEC and increase its speed (Lumpkin and Garzoli 2005).

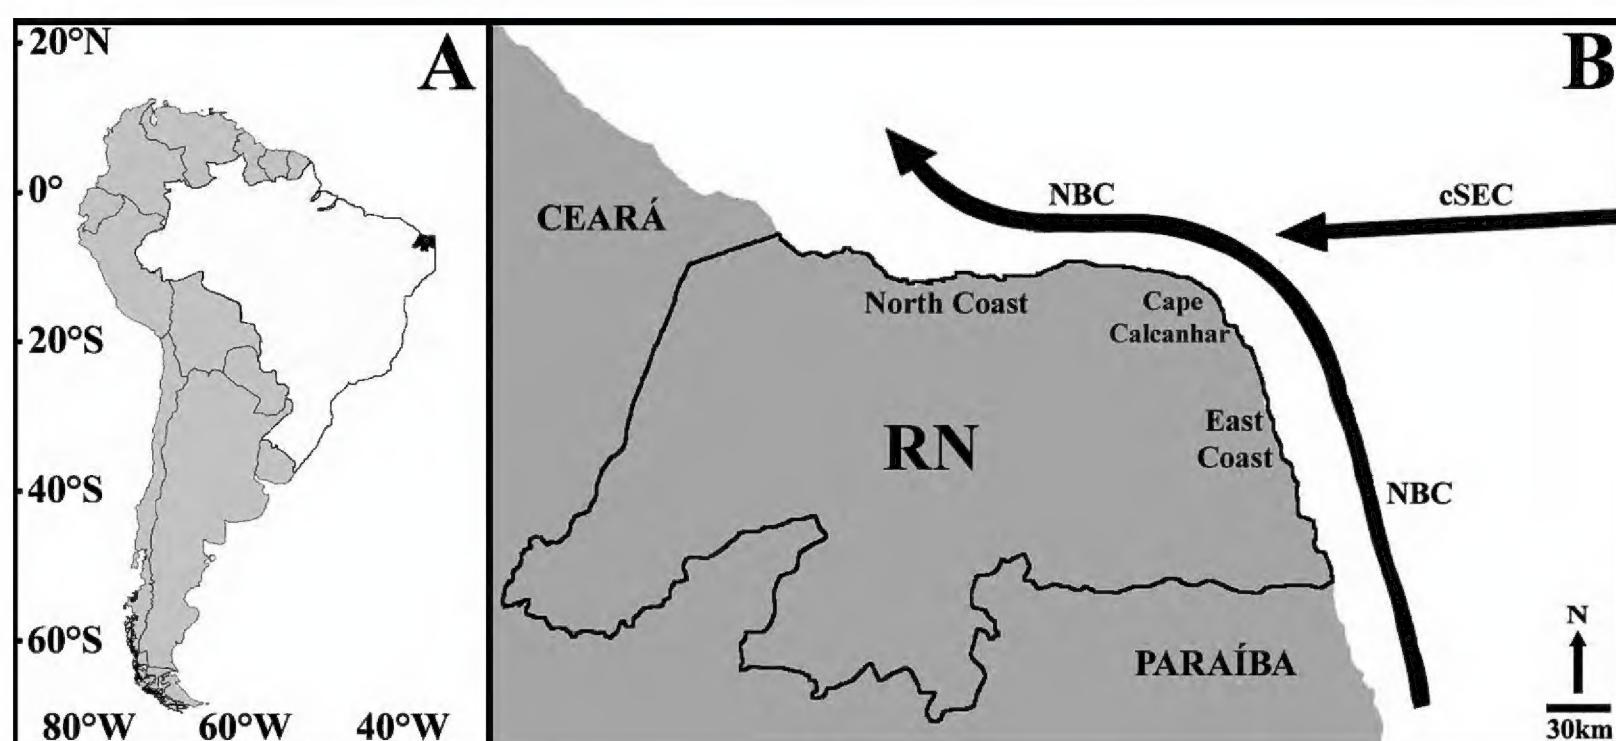

Figure 1. **A:** Geographical localization of the Rio Grande do Norte state (RN). **B:** Schematic representation of the northern and eastern coast of RN. NBC: North Brazil Current; cSEC: central branch of the South Equatorial Current.

Data collection

The records presented here were obtained between 2003 and 2013 through collection of specimens at more than 80 localities along the coast using hook and line, dip nets, trawl nets, gill nets, hand nets and plastic bags while SCUBA and free diving. During the same period, landing records of artisanal fleet were done in the main fishing ports, examining only boats fishing in localities within the limits of RN coast. Whenever possible, specimens with total length less than 60 cm were preserved and deposited in the ichthyological collection of Laboratório de Biologia Pesqueira (LABIPE) of Universidade Federal do Rio Grande do Norte (UFRN), Natal, Brazil. Additionally, literature reviews were made of fish studies carried out on the RN coast and examination of specimens deposited in the ichthyological collection at the Museu do Mar Onofre Lopes (MMOL) and the Museu de Ciências Biológicas, both from UFRN. Coastal fishes are here defined as fishes that inhabit from estuaries to the continental shelf break. On the northern coast, the continental shelf extends for 40–45 km from the beach line and breaks around 40–50 m depth (Amaro and Ferreira 2012), while on the eastern coast, it extends for 14–30 km and breaks in 50–60 m depth (Vital et al. 2010). Species occurrences in the RN are listed at coast level (records at northern coast and/or eastern coast) and the fish common name used by local fishermen is presented when existing. All species listed were recorded in this study, except those have only been reported in other studies carried out on the RN, which are remarked with “reported by”. The species list is presented according to the phylogenetic arrangement proposed by Nelson (2006) and the taxonomy classification of Eschmeyer (2015), except for the family Ariidae (*sensu* Marceniuk and Menezes 2007). The genera and species are arranged within families in alphabetical order.

RESULTS

This study recorded 459 species from two classes, 26 orders, 102 families and 264 genera, with 83 species (18% of the total number) recorded for the first time in the study area. In addition, three new records are presented for Brazilian coast and nine extensions of species geographic distribution. In the following checklist, an asterisk (*) indicates a Brazilian endemic species and a cross (+) indicates an endangered species in Brazil.

Class Chondrichthyes

Order Orectolobiformes

Family Ginglymostomatidae

Ginglymostoma cirratum (Bonnaterre, 1788) ⁺

Tubarão lixa

Coast: north and east

Family Rhincodontidae

Rhincodon typus Smith, 1828

Tubarão baleia

Coast: east

Order Carcharhiniformes

Family Triakidae

Mustelus canis (Mitchill, 1815) ⁺

Coast: unknown

Remarks: reported by Soares (1988); there are no posterior records of this species.

Family Carcharhinidae

Carcharhinus acronotus (Poey, 1860)

Cação focinhudo

Coast: north and east

Carcharhinus falciformis (Müller & Henle, 1839)

Lombo preto

Coast: north

Carcharhinus leucas (Müller & Henle, 1839)

Coast: north

Reported by Yokota (2005)

Carcharhinus limbatus (Müller & Henle, 1839)

Galha preta

Coast: north and east

Carcharhinus obscurus (Lesueur, 1818) ⁺

Coast: unknown

Remarks: reported by Soares (1988); there are no posterior records of this species.

Carcharhinus perezi (Poey, 1876) ⁺

Coast: north and east

Remarks: reported by Moura (2003) in northern coast and Feitoza (2001) in eastern coast

Carcharhinus plumbeus (Nardo, 1827) ⁺

Tubarão galhudo

Coast: north and east

Carcharhinus signatus (Poey, 1868) ⁺

Cação toninha

Coast: north and east

Galeocerdo cuvier (Péron & Lesueur, 1822)

Tubarão tigre

Coast: north and east

Rhizoprionodon lalandii (Müller & Henle, 1839)

Cação frango

Coast: north and east

Rhizoprionodon porosus (Poey, 1861)

Cação frango

Coast: north and east

Family Sphyrnidae

Sphyrna lewini (Griffith & Smith, 1834) ⁺

Tubarão martelo

Coast: north and east

Sphyrna mokarran (Rüppel, 1837) ⁺

Tubarão martelo

Coast: north and east

Sphyrna tiburo (Linnaeus, 1758) ⁺

Coast: unknown

Remarks: reported by Soares (1988); there are no posterior records of this species.

Order Lamniformes

Family Odontaspidae

Odontaspis ferox (Risso, 1810)

Coast: unknown

Remarks: reported by Menni et al. 1995

Family Alopiidae

Alopias superciliatus Lowe, 1841 ⁺

Tubarão raposa

Coast: north

Order Pristiophoriformes

Family Pristidae

Pristis pectinata Latham, 1794 ⁺

Coast: unknown

Remarks: reported by Soares (1988); the MMOL has a taxidermized specimen with approximately 40 cm total length and a rostrum with approximately 100 cm, both collected on the RN coast; probably old records and there are no posterior records of this species.

Order Torpediniformes

Family Narcinidae

Narcine bancrofti (Griffith & Smith, 1834)

Treme tremor

Coast: north and east

Narcine sp.

Treme tremor

Coast: north

Remarks: reported by Garcia Jr et al. (2010)

Order Rajiformes

Family Rhinobatidae

Rhinobatos percellens (Walbaum, 1792) ⁺

Cação viola

Coast: north and east

Order Myliobatiformes

Family Urotrygonidae

Urotrygon microphthalmum Delsman, 1941

Raia roliça

Coast: north and east

Family Dasyatidae

Dasyatis americana Hildebrand & Schroeder, 1928

Raia de areia

Coast: north and east

Dasyatis centroura (Mitchill, 1815) ⁺

Raia de pedra

Coast: north and east

Dasyatis guttata (Bloch & Schneider, 1801)

Raia pontuda

Coast: north and east

Dasyatis mariana Gomes, Rosa & Gadig, 2000 ^{*}

Raia verde

Coast: north and east

Dasyatis say (Lesueur, 1817)

Raia

Coast: north

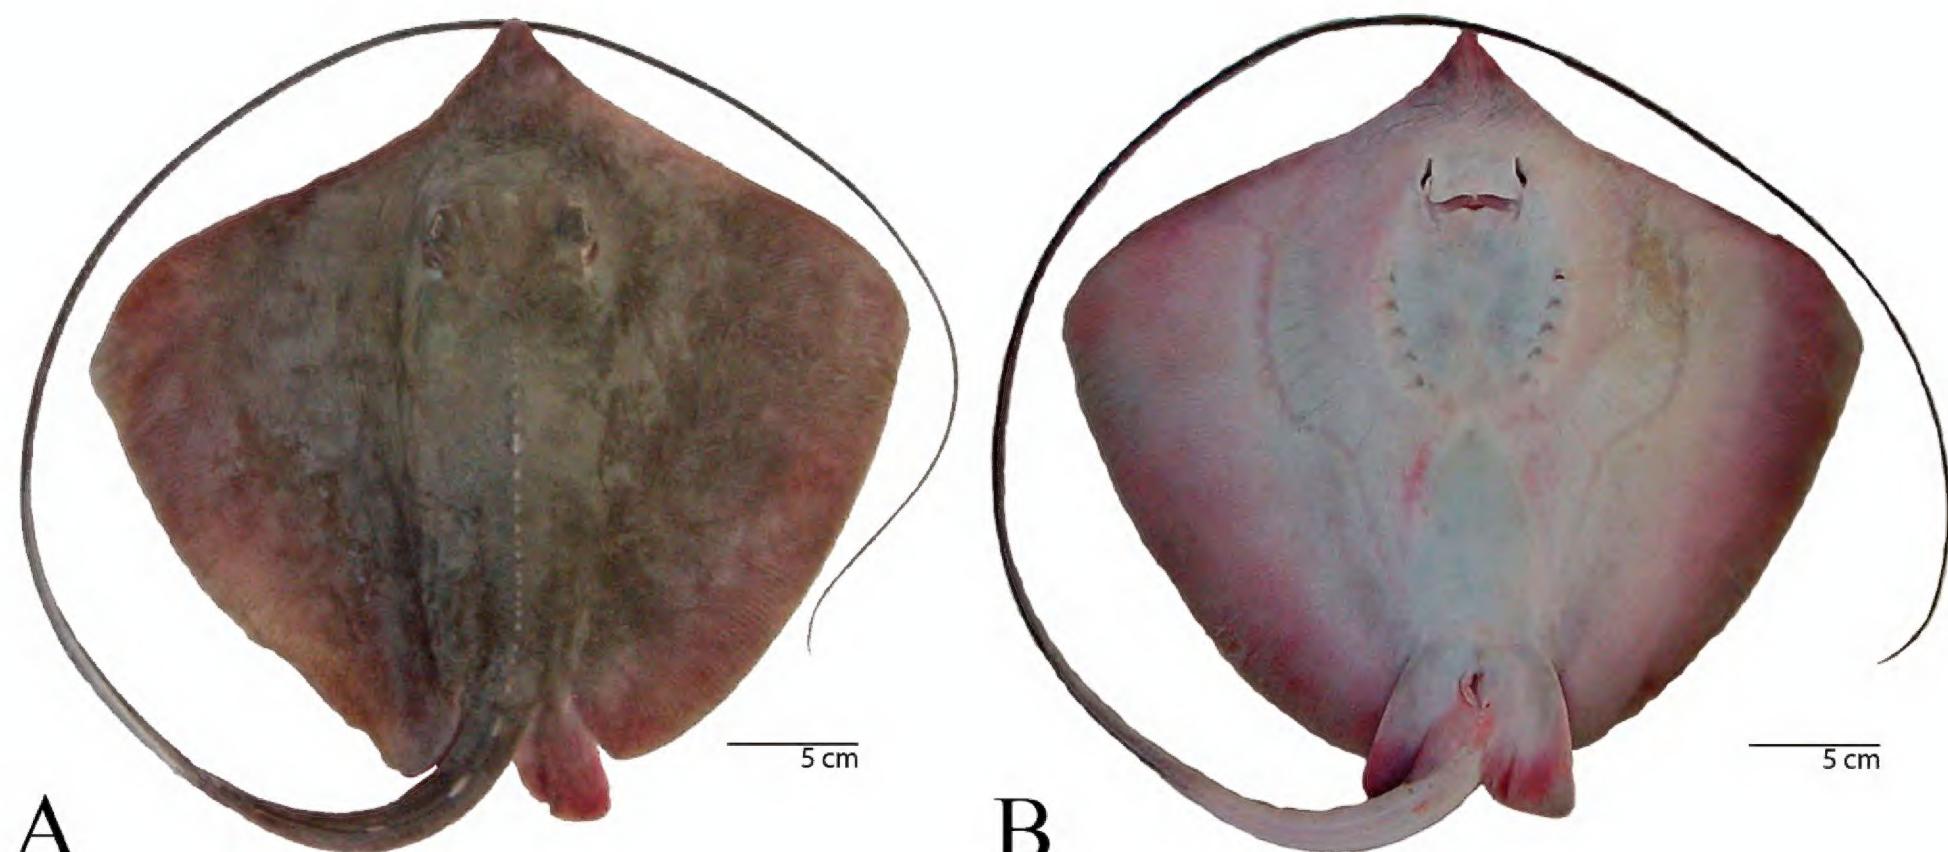

Figure 2. **A:** Dorsal view of *Dasyatis* n. sp. **B:** Ventral view of *Dasyatis* n. sp.

***Dasyatis* n. sp.**

Raia

Coast: north

Remarks: on 7 March 2006, a specimen (LABIPE 32) of the genus *Dasyatis* was collected in front of Guamaré, northern coast, on sandy substrate in 12 m depth with trawl net. The female specimen measuring 31 cm disc width and 800 g total weight, was not identified as any Atlantic species described for the genus, being similar to *Dasyatis guttata*, but with more elongated snout, with pelvic fins projected beyond the posterior margin of the disc and a longer tail (Figure 2a and 2b). This species is under description process.

Family Gymnuridae

Bagre ariaçú

Coast: north and east

Remarks: on 3 November 2006, 24 specimens (LABIPE 49-72) were collected in Pirangi beach, eastern coast, on sandy substrate in about 1 m depth with hook and line. The specimens measured between 13 and 29 cm total length and 14 and 159 g total weight (Figure 4a and 4b). Additionally, other specimens were also recorded in several localities at northern and eastern coast of RN. According to Marceniuk (2005), the species is found in Brazil from southern Bahia to Rio Grande do Sul states. Therefore, the present records are the northernmost occurrence and extends its geographical distribution.

Ginga

Coast: north and east

Remarks: on 1 January 2007, a specimen (LABIPE 146) was collected in Grossos, northern coast, in an estuary channel in 0.5 m depth with hand net, together with several specimens of *Atherinella brasiliensis*. The specimen measured 9 cm in total length and 7 g total weight (Figure 5). Additionally, other specimens were also recorded in several localities at northern and eastern coast of RN. According to Mattox et al. (2008), the species

Figure 5. *Atherinella blackburni* (photo J. Garcia Jr.).

is discontinuously found in western Atlantic Ocean in localities of Costa Rica, Panama, Venezuela and in Brazil at Alagoas, Bahia, Rio de Janeiro and São Paulo states. Thus, the occurrence on the RN coast extends the geographic distribution of this species in Brazil and may indicate that the discontinuity of records is possibly caused by misidentifications of *A. brasiliensis*, a very similar species.

Remarks: on 17 June 2009, a specimen was collected in front of Caiçara do Norte beach, northern coast, on rocky substrate in about 40 m depth by a boat fishing with gill nets. The specimen measured 29 cm total length and 380 g total weight (Figure 9). In Brazil, the species is recorded only in Trindade Island, 1160 km distant from the coast of Espírito Santo state (Gasparini and Floeter 2001) and in Pernambuco state (Oliveira and Barbosa 2010). The present record is the northernmost occurrence and extends its geographical distribution.

Remarks: on 17 May 2005, a specimen (LABIPE 25) was collected in João da Cunha reefs, northern coast, on reef substrate in about 30 m depth with fish trap. The specimen measured 23 cm total length and 62 g total weight (Figure 13). In the western Atlantic Ocean, the species is described to occur in Florida, Carolinas, Bermudas and Caribbean Sea and in Brazil on oceanic islands of Fernando de Noronha, Atol das Rocas and São Pedro e São Paulo (Menezes et al. 2003). Additionally, Rocha et al. (2005) reported the collect of two individuals of this species on the northeastern coast of Brazil, but without specifying the occurrence site or fish data. Thus, present record confirms the occurrence of this species on the Brazilian coast.

Lachnolaimus maximus (Walbaum, 1792)

Coast: east

Remarks: on 28 December 2010, a spear gun sport

fishermen collected a specimen in front of Muriú beach, eastern coast, on rocky substrate in about 30 m depth. The specimen measured 56 cm total length and 5600 g total weight (Figure 14) and unfortunately, it was not possible to preserve it. Luiz et al. (2013) reported the presence of this species on the northeastern coast of Brazil, but without specifying the occurrence site or fish data. Thus, present record confirms the occurrence of this species on the Brazilian coast.

Canthigaster jamestyleri Moura & Castro, 2002

Baiacú mirim

Coast: north

Remarks: on 12 August 2005, a specimen (LABIPE 26) was collected in the Urca do Minhoto, northern coast, on reef substrate in about 20 m depth with plastic bag while SCUBA diving. The specimen measured 6 cm total length and 10 g total weight (Figure 15). *Canthigaster jamestyleri* differs from all Atlantic congeners (more similar to *C. figureiredoi*) by the presence of a small irregular dark spot on the dorsal fin base and the absence of dark dorsal and ventral margins on the caudal fin (Moura and Castro 2002). In the western Atlantic Ocean the species is described to occur in the southern USA and Gulf of

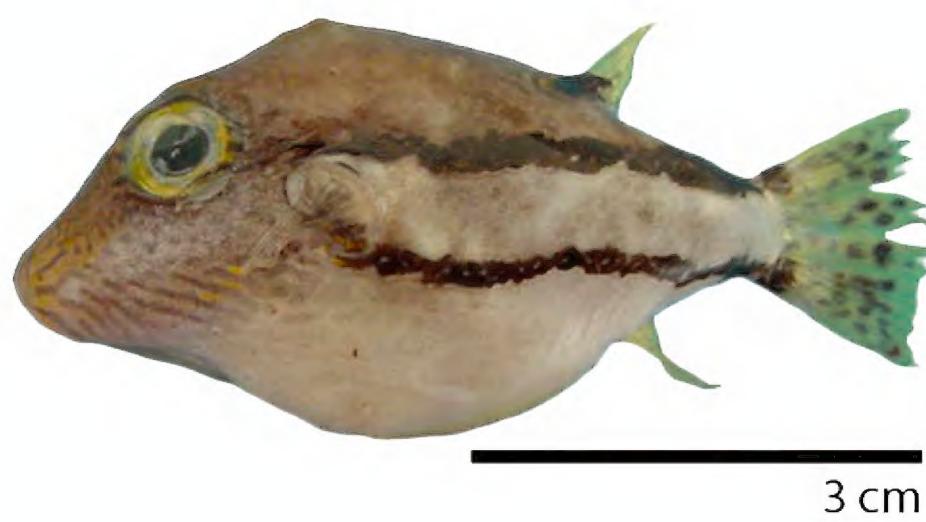

Figure 15. *Canthigaster jamestyleri* (photo J. Garcia Jr.).

Mexico (Moura and Castro 2002). Thus, present record is the first occurrence of this species on the Brazilian coast.

DISCUSSION

At present, 459 species of coastal fishes are known from the Rio Grande do Norte state (RN). Soares (1988) recorded the occurrence of *Lycengraulis barbouri* (a synonym of *L. batesii*), *Trachinotus glaucus* (a synonym of *T. ovatus*) and *Ogcocephalus radiatus* in RN coast. By analyzing specimens identified as belonging to these species at MMOL, it was verified that in fact, they are *L. grossidens*, *T. goodei* and *O. vespertilio*, respectively. According to the latest compilation, 1,297 species of marine fishes were found on the Brazilian coast (Menezes et al. 2003), of which about 35% is recorded in the coast of RN. Most species presented here (358) was recorded on both coasts; however, 52 species were exclusively recorded on the northern coast and 42 species exclusively on the eastern coast. These exclusive records may be the result of differences in habitat characteristics between these coasts. As example, estuarine species like *Anchoa januaria*, *A. tricolor*, *Lycengraulis batesii*, *Achirus achirus* and *Gymnachirus nudus* were recorded only in northern coast, where are the larger estuarine habitats of RN. Otherwise, oceanic species like *Polymixia lowei*, *Thunnus atlanticus*, *Sphoeroides pachygaster* and *Ranzania laevis* were recorded only in the eastern coast, where the continental shelf is narrower. With regard to the number of species, the results demonstrate that the coastline of RN is richer than it was suspected, and that this can be considered reasonably known to date. However, surveys on deeper habitats as well as the use of higher sampling effort may result in additional records. The composition of fish fauna of RN coast is recognized for having high similarity to the fish fauna of the neighbor states of Paraíba and Pernambuco (Floeter et al. 2001; Moura 2003; Feitoza et al. 2005; Freitas and Lotufo 2014). However, this similarity was always tested using the fish fauna of a few localities of RN rather than all species occurring along the coast. Previously zoogeographical

hypothesis based only on small-scale local lists or on few families should be tested using a comprehensive regional checklist, as presented herein. Of the 459 species recorded in RN, 27 are Brazilian endemic fishes and 37 species have recently been included in the National List of Endangered Fauna, under some degree of threat (MMA, 2014). Of these 37 species, 27 are captured by commercial fishing in RN, and now legally prohibited from being caught and marketed. The large number of new records for the RN coast (83) reflects the existence of few local inventories and shows how the lack of studies influences the state of knowledge in a specific area. Ultimately, this can affect the quality and effectiveness of management strategies applied to the fish stocks. As an example, between 2000 and 2005, fishery monitoring sponsored by the government on the RN coast registered a capture of approximately 2,385 tons in the category named “serra”, represented by *Scomberomorus brasiliensis* (MMA 2006). However, our records show that *S. regalis*, a morphologically similar species, is also captured simultaneously in the same habitats as *S. brasiliensis*, and is included in the same category. The same occurs with species of *Centropomus* spp., *Coryphaena* spp., *Epinephelus* spp., *Mugil* spp., *Sparisoma* spp., family Ariidae and order Pleuronectiformes. Therefore, only one stock is being evaluated when in fact there are two or more. Only with a better understanding of the local fish fauna and a monitoring designed by species, it will be possible properly to monitor the level of exploitation of local fish stocks. In this sense, this checklist provides a great increment in the knowledge of the coastal fishes of RN and represents the first steps for improve the fishery management of this area.

ACKNOWLEDGEMENTS

This work represents part of the M.Sc. research of J. Garcia Jr. who thanks Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support. We are grateful to Waldecir S. Costa (*in memoriam*) and Wellington S. Xavier for helping with specimens collections. We thank Ronaldo Barradas for providing his collect data of *Lachnolaimus maximus*. Cláudio L.S. Sampaio and Bertran M. Feitoza greatly helped with the identification of some specimens.
